The GPU can process a plurality of graphics workloads (e.g., vertex, tessellation, rasterization, pixel and compute workloads). Some of these graphics workloads are parallelizable across GPUs, where each GPU is tasked to process a subset of the workloads. In some instances, the GPU may be tasked to process a workload of graphics primitives. For example, the GPU may be tasked to perform drawing workloads for rasterization of a single or multiple triangles. The GPU can process the graphics workloads in hardware of the GPU, and then communicate the results of the workloads to a graphics memory for further processing of the graphics workloads. With some geometry processing units, a GPU does not have access to a shader for programmable processing. Accordingly, the GPU cannot modify graphics primitives during processing. For instance, the GPU cannot change colors of surfaces within the graphics primitives, change the style of a surface within the graphics primitives, or change the color of a surface, once the GPU is tasked to perform the drawing workload.Q: How can I link a C++/CLI application to one of my DLL's? We are working on a Windows application that uses C++/CLI. When we build our application, we have the option of linking to any of our DLL's. Is there a way of linking to a DLL inside a DLL? For instance,
