The sound transmission and sound anisotropy properties of a porous medium were investigated using a coupled-instrument technique. A compact array of thirteen microphones was used to measure the pressure wave directly, as well as the displacement wave at a fixed distance from the source. The porous media considered were sand, aggregated sediment, and limestone. The corresponding acoustic properties of these porous media are compared with those of homogeneous elastic solid media. The measurements were done for different sound propagation distances and for different angles of incident sound wave. The results indicate that the porous media can increase the transmission efficiency, without any changes in the frequency and velocity of the pressure 2d92ce491b
