- MS Access mdb files - MS Access.Macro Definition files - UML Model versions - PDFs - PNGs - XLSX - CSV - All of them Macro Definitions (MDBs): Macros are a cool way of speeding up the workload of the coder. In most cases, instead of creating a prototype, the user should create a macro, then write one or several lines of code to simulate many more lines of code. This way, we can emulate the basic logic of what we want to design without the hassle of creating a prototype. To use this feature, you need a special format of an Access mdb file, called macro definition file. The working of macro definition files is simply that they are just a way to record the macro parameters that you want to use. When we will use a macro, the access will then try to interpret this file and make the appropriate changes to the actual mdb. It is generally a good idea to include a copy of the Macro Definition file in the mdb, so that your code is easily updated without needing to do any changes to the real mdb itself. This file is called the Macro Definition File, it is simply a.mdb file with the extension.macrdef. It will also be necessary to have a copy of the UML.mdx file, also included in the same directory as the.macrdef, in case you want to use a different model than the one specified in the.macrdef file. Macros are stored as a data entry in the table named Macros. Here is a small example to show the general structure of a Macro Definition File: Macro Parameters: macro1, macro2 and macro3 are the parameters we are going to use. These are named parameters, which means that if we want to include a parameter named title, 1d6a3396d6
